

A procedure or function which calls itself is a recursive routine.

Consider the following function, which computes  $N! = 1 * 2 * \dots * N$

```
int Factorial(int n) {  
    int Product = 1,  
        Scan    = 2;  
  
    while ( Scan <= n ) {  
        Product = Product * Scan ;  
        Scan = Scan + 1 ;  
    }  
    return (Product) ;  
}
```

Now consider a recursive version of Factorial:

```
int Factorial(int n ) {  
    if ( n > 1 )  
        return( n * Factorial (n-1) );  
    else  
        return(1);  
}
```

- Every recursive algorithm can be implemented non-recursively.  
recursion  $\Leftrightarrow$  iteration
- Eventually, the routine must not call itself, allowing the code to "back out".
- Recursive routines that call themselves continuously are termed:  
infinite recursion  $\Leftrightarrow$  infinite loop
- Problem with this recursive factorial implementation? **Negative numbers!**
- Recursion is very inefficient at runtime.

Here is a recursive function that takes an array of integers and computes the sum of the elements:

```
// X[]      array of integers to be summed
// Start    start summing at this index . . .
// Stop     . . . and stop summing at this index
//
int SumArray(const int X[], int Start, int Stop) {

    if (Start > Stop || Start < 0 || Stop < 0)    // error check
        return 0;
    else if (Start == Stop)                      // base case
        return X[Stop];
    else
        return (X[Start] + SumArray(X, Start + 1, Stop));
}
```

The call:

```
const int Size = 5;  
int X[Size] = {37, 14, 22, 42, 19};  
SumArray(X, 0, Size - 1);    // note Stop is last valid index
```

would result in the recursive trace:

SumArray(X, 0, 4)	// return values: // == <b>134</b>
↓ return ( X[0] + SumArray(X, 1, 4) )	// == 37 + 97
↙ return ( X[1] + SumArray(X, 2, 4) )	// == 14 + 83
↙ return ( X[2] + SumArray(X, 3, 4) )	// == 22 + 61
↙ return ( X[3] + SumArray(X, 4, 4) )	// == 42 + 19
↙ return X[4]	// == 19

```
// X[]      array of integers to be sorted
// Start    start selection pass here . . .
// Stop     . . . and stop the search pass here
//
void SelSort(int X[], int Start, int Stop) {

    int Begin = Start,
        Check ,
        SmallSoFar = Begin;
    int tmpInt;

    if (Start < Stop) {
        for (Check = Begin + 1; Check <= Stop; Check++) {
            if (X[Check] < X[SmallSoFar])
                SmallSoFar = Check;
        }
        tmpInt = X[Begin];
        X[Begin] = X[SmallSoFar];
        X[SmallSoFar] = tmpInt;

        SelSort(X, Start + 1, Stop);
    }
}
```

The call:

```
const int Size = 5;  
int X[Size] = {37, 14, 22, 42, 19};  
SelSort(X, 0, Size - 1);    // note Stop is last valid index
```

would result in the recursive trace:

	// Contents of X when call occurs:
SelSort(X, 0, 4)	// {37, 14, 22, 42, 19}
SelSort(X, 1, 4)	// {14, 37, 22, 42, 19}
SelSort(X, 2, 4)	// {14, 19, 22, 42, 37}
SelSort(X, 3, 4)	// {14, 19, 22, 42, 37}
SelSort(X, 4, 4)	// {14, 19, 22, 37, 42}
